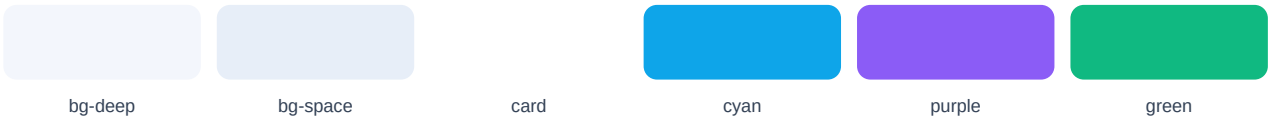
Seevora Project Theme, Animation, and AI Model Analysis

A concise technical overview of the frontend design system, motion behavior, 3D visual layer, and how the project positions AI model usage.



Executive Summary

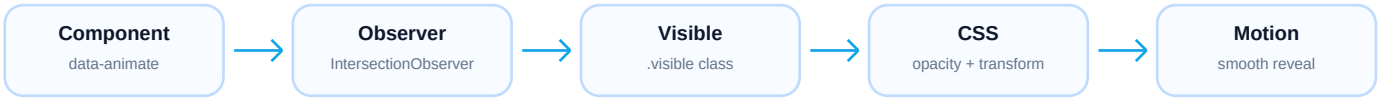
The project uses a light 3D glassmorphism theme: soft blue-gray backgrounds, translucent white cards, cyan and purple accents, smooth scroll-reveal animations, and a premium AI-inspired 3D robot scene. It is built with React, Vite, CSS design tokens, React Three Fiber, Drei, and Three.js.

Important accuracy note: the current frontend does not connect to a specific AI provider such as OpenAI, Gemini, Claude, or a custom inference endpoint. The website content describes Seevora as building custom AI models and AI pipelines, but the app code is presentation-only.

Theme Used In This Project

Area	Implementation	Purpose
Theme style	3D glassmorphism design system	Creates a modern enterprise AI/SaaS look with depth and translucency.
Base palette	#f3f6fc, #e7eef8, #ffffff	Keeps the interface bright, clean, and professional.
Accent palette	#0ea5e9 cyan, #8b5cf6 purple, #10b981 green	Signals AI, automation, progress, and highlights.
Typography	Inter for body, Outfit for headings	Balances readability with a bold SaaS headline style.
Cards	Translucent white, blurred background, subtle borders	Builds the glass effect and separates content without heavy panels.
Layout	1200px container, large 120px section padding	Gives the landing page a spacious enterprise feel.

How The Animation System Works



Most page-entry animation is attribute-driven. Components add data-animate or a value such as data-animate="slide-left". In App.jsx, an IntersectionObserver watches those elements and adds the visible class when they enter the viewport. CSS then transitions opacity and transform to reveal the element.

- Default reveal starts at opacity 0 and translateY(50px), then transitions to opacity 1 and translateY(0).
- Variants include slide-left, slide-right, scale-in, and tilt-in by changing the initial transform.
- Reusable transition tokens define fast, smooth, and spring-like timing curves.
- GlassCard adds mouse-based 3D tilt by calculating cursor position and applying rotateX, rotateY, and translateZ transforms.
- Stats counters use requestAnimationFrame with an easeOutExpo curve after an IntersectionObserver detects visibility.
- The navbar changes from full pill navigation to a compact floating state based on scroll direction and position.

3D And Motion Layer

The hero visual uses React Three Fiber and Drei to render an AI-style robot scene inside a WebGL Canvas. The robot has a cursor-following head, pulsing eyes, a spinning chest core, floating hands, orbital rings, particles, and soft cyan/purple lighting. Drei Float adds a gentle hover effect, while useFrame updates scene motion every rendered frame.

- Canvas is configured with antialiasing, alpha transparency, and high-performance preference.
- PerspectiveCamera sets the 3D viewpoint for the hero robot.
- Three.js materials, lights, meshes, and particles create the futuristic AI look.
- CSS fallback orb visuals appear through React Suspense while the 3D scene loads.

AI Model Usage

The website positions Seevora as an AI automation company that builds production-grade AI systems, custom AI SaaS products, and AI pipelines. Copy in the Solutions and Workflow sections says the team uses the right models for each sub-task, validates models for accuracy, and integrates AI into existing business systems.

From a code perspective, this repository currently contains the marketing/presentation layer only. There is no frontend call to an AI model API, no model configuration file, and no provider-specific dependency. If a backend is added later, this site can describe model usage more concretely, for example: LLM for document understanding, classifier for routing, embedding model for search, or vision model for image/document extraction.

Layer	Current status	Recommended wording
Frontend	React/Vite presentation layer	AI-themed product website and user acquisition flow.
3D visual	React Three Fiber robot scene	Represents intelligent automation visually; not an ML model.
AI model	Not hardcoded in this repo	Custom AI models/pipelines selected per business process.
Integration	Marketing copy references CRMs, ERPs, databases	AI augments existing systems without rip-and-replace.

Key Files Reviewed

- src/index.css - design tokens, glass cards, keyframes, scroll reveal states, navbar motion, responsive layout.
- src/App.jsx - route handling and global IntersectionObserver for data-animate elements.
- src/components/landing-page/AIScene3D.jsx - WebGL/Three.js robot, particles, lights, and per-frame animation.
- src/components/landing-page/GlassCard.jsx - cursor-driven 3D tilt interaction.
- src/components/landing-page/Stats.jsx - animated numeric counters.
- package.json - React, Vite, Three.js, @react-three/fiber, and @react-three/drei dependencies.

Conclusion

The project theme is best described as a light enterprise AI glassmorphism interface with 3D WebGL hero visuals. Animation is split between CSS scroll-reveal transitions, JavaScript viewport triggers, cursor-based card tilt, counter animation, and Three.js frame-loop motion. The AI model story is part of the product positioning today; the current frontend does not implement model inference directly.
